Effects of Hormones on Cultivation of
Tricholoma matsutake Mycelia

A mixture of callus of Akamatsu and mycelium of Tricholoma matsutake was obtained from roots of it with MS medium containing 0.01μM of 2, 4-D and 0.1μM of kinetin. Colony, which formed polymer of mycelia of T. matsutake, was obtained with MS medium containing 0.01μM of IAA and 0.01μM of kinetin. Therefore, it may be possible to cultivate T. matsutake by means of using hormones such as IAA and kinetin on the sawdust medium.

Introduction

The basidiomycete Tricholoma matsutake is a mushroom which has been eaten since old times in Japan. Ogawa and Hamada reported that the fruiting body primordium of T. matsutake could be developed by an artificial procedure. However, it is generally recognized that the artificial cultivation of a perfect fruiting body is very difficult with T. matsutake. This report deals with the formation of polymerized mycelia of T. matsutake.

Materials and Methods

Separation, Induction and cultivation of callus and mycelium.

Current roots of Akamatsu (Japanese red pine) were collected from Tanba-sasayama. After washing with running tap water, the roots were surface-sterilized with 70% ethanol for 30 sec, further sterilized with 1% sodium hypochlorite aqueous containing a few drops Tween 80 for 5 min, and then rinsed three times in sterilized distilled water.

The peeled roots were inoculated Murashige and Skoog medium (MS medium) solidified by 0.8% agar, whose pH was adjusted to 5.8, and culture for callus induction at 25°C under fluorescence illumination of about 2,000 lux (16 hour/day) throughout the period. 2,4-dichlorophenoxyacetic acid (2,4-D) and kinetin were added to the culture medium in various concentrations (0, 0.01, 0.1, 1μM). The induced callus was subcultured in the dark at one-month intervals on the same solid medium as that for callus induction.

Mycelia of matsutake were cultured with MS medium containing indole-3-acetic acid (1μM) and kinetin (0, 0.01, 0.1, 1μM) at 25°C in the dark.

Results and Discussion

Separation, induction and cultivation of callus and mycelium.

Figure 1 shows the roots of Akamatsu, which was obtained from Tanba-sasayama. Mycelium of T. matsutake was isolated from the root, as shown in Fig.2. Mixture of callus of Akamatsu and mycelium of T. matsutake was obtained with MS medium containing 0.01μM of 2,4-D and 0.1μM of kinetin (Fig.3(a), (b)).

And then callus of Akamatsu and colony of T. matsutake were purified from the mixture, as
shown in Fig.3(c) and (d). Figure 4 shows electronic scanning micrographs of the mixture of callus and mycelia.

Effects of IAA and kinetin on the formation of polymerized mycelia of *T. matsutake*.

Figure 5 shows the effects of IAA and kinetin on the formation of polymerized mycelia of *T. matsutake*. Colony, which formed polymer of mycelia, was obtained with MS medium containing 0.01µM of IAA and 0.01µM of kinetin (Fig.6). On the other hand, polymer of mycelia was not obtained with MS medium without hormone. It is suggested that hormones such as IAA and kinetin promote to polymerize mycelia of *T. matsutake*. Polymer of mycelia, which seems like to be fruit body, was obtained with MS medium containing 0.01µM of IAA and 0.01µM of kinetin. Therefore, it may be possible to cultivate *T. matsutake* by means of using hormones such as IAA and kinetin on the sawdust medium.
